This proposal is designed to understand the regulation of the enzymes that regulate the synthesis and utilization of the nucleic acids that make up cellular DNA. The enzymes, purine and pyrimidine nucleotidase, form a nucleotidase superfamily that is regulated by an accessory protein. This protein is called P nucleotidase. The two members of this superfamily, purine and pyrimidine nucleotidases, are prototypical examples of the enzymes that provide the purine and pyrimidine components for DNA synthesis. The regulation of these nucleotidases is of considerable interest because they are the only enzymes that can use GTP as a substrate. Thus, the regulation of the nucleotidases is likely to be important for the regulation of all GTP-dependent biological processes. The members of this superfamily are organized into two distinct families. P nucleotidase is a member of the purine nucleotidase family. In contrast, the enzymes of the pyrimidine nucleotidase family lack the accessory protein and are regulated by metal ions and organic phosphates. The specific aims of this proposal are to understand the regulation of purine and pyrimidine nucleotidases at a molecular 81e310abfb
